Fish Protection Technologies and Downstream Fishways

Dimensioning, Design, Effectiveness Inspection

July 2005
Fish Protection Technologies and Downstream Fishways

Dimensioning, Design, Effectiveness Inspection

July 2005
The DWA – German Association for Water, Wastewater and Waste – is in Germany spokesman for all comprehensive water queries and is intensively committed to the development and distribution of a secure and sustainable water supply. It works as a politically an economically independent organisation professionally in the fields of water management, sewage, waste and soil protection.

DWA is in Europe the association with the largest number of members within this field and therefore takes up a special position. This is because it provides professional competence regarding standardisation, professional training and information towards the public. Approximately 14,000 members represent the experts and executives from communes, universities, engineering offices, authorities and enterprises.

The main emphasis of its activities is on the acquirement and update of a uniform technical set of rules and standards as well as the cooperation on the list of technical norms on a national and international level. In this connection not only are the technical scientific topics involved, but also the economic and legal interests of the environment and water pollution forms a part.
Foreword

Since the state-of-the-art of fish passes has been considerably improved, which not least is owed to the DVWK-publication 232 (1996), the demand for free passage for downstream migrating fish gains increasing importance. Next to an ecologically oriented operation management of dams and inlet works, fish protection facilities and downstream fishways are the only possibility to reduce the obstructing effect of in-stream obstacles (dams and weirs etc.) for migratory fish and to restore river continuity.

Fish protection facilities and downstream fishways in Germany have so far been built in a small number only. When dealing with this topic, it was discovered that the knowledge available was seriously insufficient with respect to the migratory behaviour and the functioning and application of fish protection facilities and downstream fishways. Application oriented research concerning the migratory behaviour of indigenous fish has started only recently, and individual fish protection facilities and downstream fishways were subjected to operational checks. Against this background, the knowledge and experience available in foreign countries had substantially to be taken as reference for this publication. It is therefore the main intention of this publication to contribute to intensified efforts for the eco-technical optimization of installations to ensure fish protection and downstream fish migration.

The present volume of the ATV-DVWK-Topics first of all deals with biological principles and explains the mechanisms of fish migration, which need to be considered as a vital precondition for functioning fish protection technologies and downstream fishways. General comments on obstacles follow, which cover all types of dams according to DIN 19700, including operational installations like weirs, hydropower plants and inlet works as well as sluices which will obstruct or delay the migration of fish and / or present hazards for migrating fish. The following technical recommendations for the design, hydraulic dimensioning and effectiveness of various migratory installations on the one hand differentiate between protection technologies, that prevent fish from entrainment into dangerous areas, and downstream fishways on the other hand, that provide fish with a safe passage into the tailwater of obstacles. These chapters are complemented by presentations of fish collection and transportation systems, descriptions of fish-friendly turbines, as well as alternative procedures, and finally offer suggestions for an installation management that is adjusted to migratory fish. Also frame conditions for planning and permission as well as legal matters are taken into consideration.
Fish Protection Technologies and Downstream Fishways

The Technical Committee “Hydraulic Engineering and Hydraulic Power” of the ATV-DVWK (now DWA) has installed the interdisciplinary Working Group WW-8.1 “Fish Protection Technologies and Downstream Fishways” to assess the knowledge available on the construction and operation of such installations. The following representatives of consulting companies, engineering consultants, energy supply companies, water associations and specialized authorities have cooperated in the preparation of this publication.

ADAM, Beate  Dr. Dipl.-Biol., Specialist for Fishery Management, Antrifttal (Speaker)
BOSSE, Rainer  Dipl.-Ing., HAR PEN AG, Dortmu t (Deputy Speaker)
DUMONT, Ulrich  Dipl.-Ing., Ingenieurburo Floecksmuehle (Floecksmuehle Consulting Engineers), Aachen
HADDERINGH, Rolf  Dipl.-Biol., KEMA Power Generation & Sustainables, Arnheim, The Netherlands
JOERGENSEN, Lothar  Dipl.-Biol., Oberfischereirat, Struktur- und Genehmigungsdirektion Nord (Head Office Structure and Approval North), Koblenz
KALUSA, Bernhard  Dipl.-Ing. E.ON Wasserkraft GmbH, Werkgruppe Lech (E.ON Hydropower Ltd.), Landsberg
LEHMANN, Gunther  Dipl.-Ing., EnBW Ingenieure GmbH, Stuttgart
PISCHEL, Rupert  Dipl.-Ing. Wupperverband (Wupper Association), Wuppertal
SCHWEVERS, Ulrich  Dr. Dipl.-Biol., Institut für angewandte Oekologie (Institute for Applied Ecology)

The work has been subjected to a public appeal procedure prior to its publication, of which all objections received have been carefully reviewed and where suitable incorporated in the present publication. Thanks shall hereby be extended to all senders of constructive objections and remarks. Our special appreciation and thanks are also addressed to the Vereinigung Deutscher Elektrizitätswerke (VDEW e.V. - Association of German Power Plants), representatives of the fishing trade, manufacturers of turbines, trash rack and screen cleaning machines as well as fish protection facilities, development institutes for hydropower technologies, dam operators as well as specialists from authorities and associations, who have supported our work with technical contributions and advice. Furthermore, we are grateful to the many foreign specialists, whose expertise has become a vital contribution to the success of this work.

Antrifttal, May, 2004                                                      Beate Adam

Table 3.3: Proportion of hydropower used for the generation of electric power in the Federal States of Germany in the year 1995 (from: VDEW, 1996) .................................................................................................................. 56
Table 3.4: Proportion of hydropower used for the generation of electric power worldwide (from ASE, 1997) .................................................................................................................................................. 57
Table 3.5: Grouping of different types of hydropower plants ................................................................................................................................. 57
Table 3.6: Typifying hydropower plants (from GIESECKE & MONSONY, 1998) ........................................................................................................ 58
Table 4.1: Total number and average rate of mortality of fish registered over 111 days of netting examinations at the Dettelbach hydropower plant on the Main river (taken from HOLZNER, 1999) .................................................................................................................................................. 72
Table 5.1: Permissible approach velocities at almost vertical, rectangular to the flow arranged mechanical barriers ($\alpha = 80 - 90^\circ$, $\beta = 90^\circ$) .................................................................................................................................................. 89
Table 5.2: Relevant body dimensions and proportions of fish of different body shapes (SCHWEVERS, 2004) .................................................................................................................................................. 101
Table 5.3: Relative bigness of the fish body $K_{thick}$ of various species .................................................................................................................. 102
Table 5.4: Limit values of the permissible clear width of impassable mechanical barriers in dependence on the target species .................................................................................................................................................. 104
Fish Protection Technologies and Downstream Fishways

Table 5.5: Coefficient ($\chi$) in dependence on the approach angle of the velocity ($\delta$) (figure 5.27) and the ratio ($s/d_R$) (GIESECKE & MOSONYI, 1997) ................................................................. 107

Table 5.6: Technically conditioned maximum screen widths at hydropower plants (Details according to RWE POWER AG and INGENIEURBUERO FLOECKSMUEHLE, verified on the basis of data available from MOSONYI (1966)) ......................................................... 110

Table 5.7: Results of selected control examinations of the effectiveness of Louvers ............................................ 112

Table 5.8: Typical dimension of Wedge-Wire Screens .................................................................................. 115

Table 5.9: Measured screen losses at a Wedge-Wire-Screen without clogging ................................................. 115

Table 5.10: Loss coefficient at screens made of wires .................................................................................. 118

Table 5.11: Efficiency of drum screens in the USA assessed with fry and smolts of Pacific salmon species as target species. Since the velocity indicated is not clearly defined, it is to be assumed that the standard velocity has been taken as basis. .................................................. 121

Table 5.12: Mortality rate of different fish species in the drum screen Bergum (The Netherlands) at an approach velocity of 0.7 to 0.8 m/s and a mesh width of 5.0 mm (HADDERINGH, 1978) ........................................ 122

Table 5.13: Reports on experiences made with electrical barriers ................................................................. 129

Table 5.14: Identification of usually used lamp types .................................................................................. 132

Table 5.15: Deterrent effect of bulbs, mercury-vapour lamps and fluorescent lamps at thermal power plants (T) and hydropower plants (W) ........................................................................................... 133

Table 5.16: Deterrent effect of stroboscope lamps at thermal power plants (T) and hydropower plants (H) ................................................................................................................................. 135

Table 5.17: Results achieved with experiments with acoustic barriers ............................................................ 137

Table 5.18: Results of examinations on the mortality of fish in screw-impeller pumps (TAFT, 1986) .............. 141

Table 5.19: Examples of dimensions of the intake of operative bypasses .......................................................... 146

Table 5.20: Recommendations of various US-States for normal and tangential velocities at inclined arranged screens intended for the protection of fish larvae and young fish. The velocities are measured at a distance of 76 mm to the barrier ........................................................................................................... 161

Table 5.21: Results of effectiveness inspections on inclined arranged screens in the USA ......................................................... 164

Table 5.22: Deterrent rate and mortality of fish at screens in the turbine inflow of hydropower plants in the catchment area of the Columbia river (Washington State, USA) (TAFT, 1986) ................................................ 166

Table 5.23: Results of examinations on downstream migrations of eel in the rivers Else, Emmer and Lippe (North Rhine Westphalia, Germany) (BARTMANN & SPAEH, 1998; RATHCKE, 1997; SPAEH, 2001b) in comparison with catches of eel in Dorlar on the Lahn river (Hesse, Germany) (ADAM, 1999) ......................................................... 168

Table 5.24: Amount of silver eel caught annually in fyke nets in front of the 10 Moselle power plants in North Rhine Westphalia (Germany) ................................................................................................................................. 181

Table 5.25: Methods employed for verifying the reliability of the MIGROMAT® (ADAM, 2004) .............. 185

Table 6.1: Fyke-net dimensions of various examinations ................................................................................. 194
